Random variables

Aim

- The scope is the generation of **independent** random variables X_1, X_2, ... X_n with a **given distribution**, $F_x(x)$, (or probability density function [pdf]).
- We assume we have access to a supply (U_i) of random numbers, independent samples from the uniform distribution on $]0,\ 1[$.
- Our task is to transform U_i into X_i.

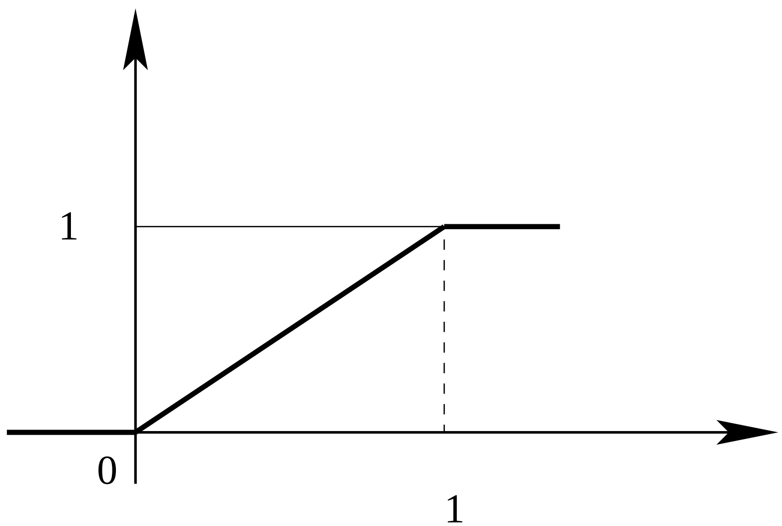
Generation of (pseudo)random variates

- Inverse transformation techniques
- Composition methods
- Acceptance/rejection methods
- Mathematical methods

Uniform distribution I

Our norm distribution or building brick, $U_i \sim U(0,1)$

$$f(x) = 1 \quad F(x) = x \quad \text{for} \quad 0 \leq x \leq 1$$

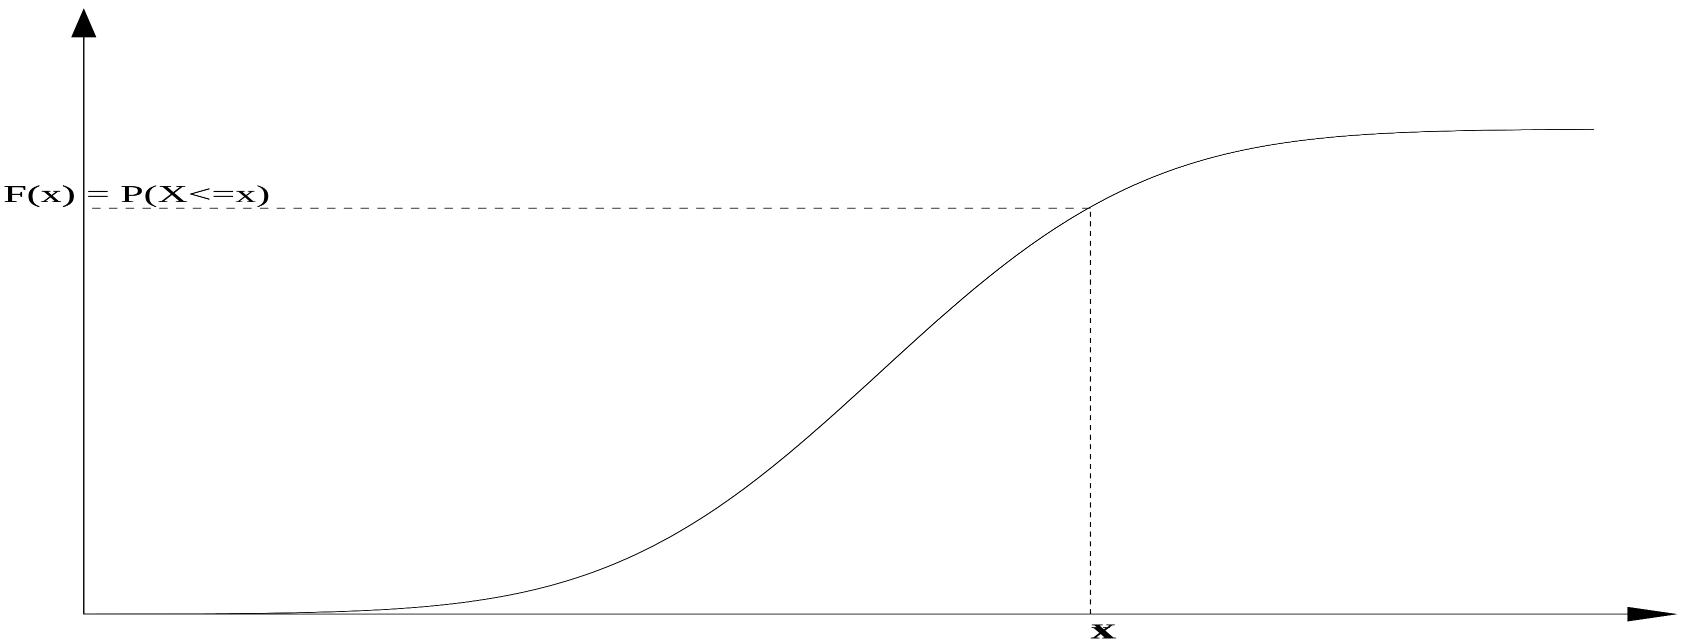


$$\mathbb{E}(U_i) = \frac{1}{2} \quad \mathbb{V}(U_i) = \frac{1}{12}$$

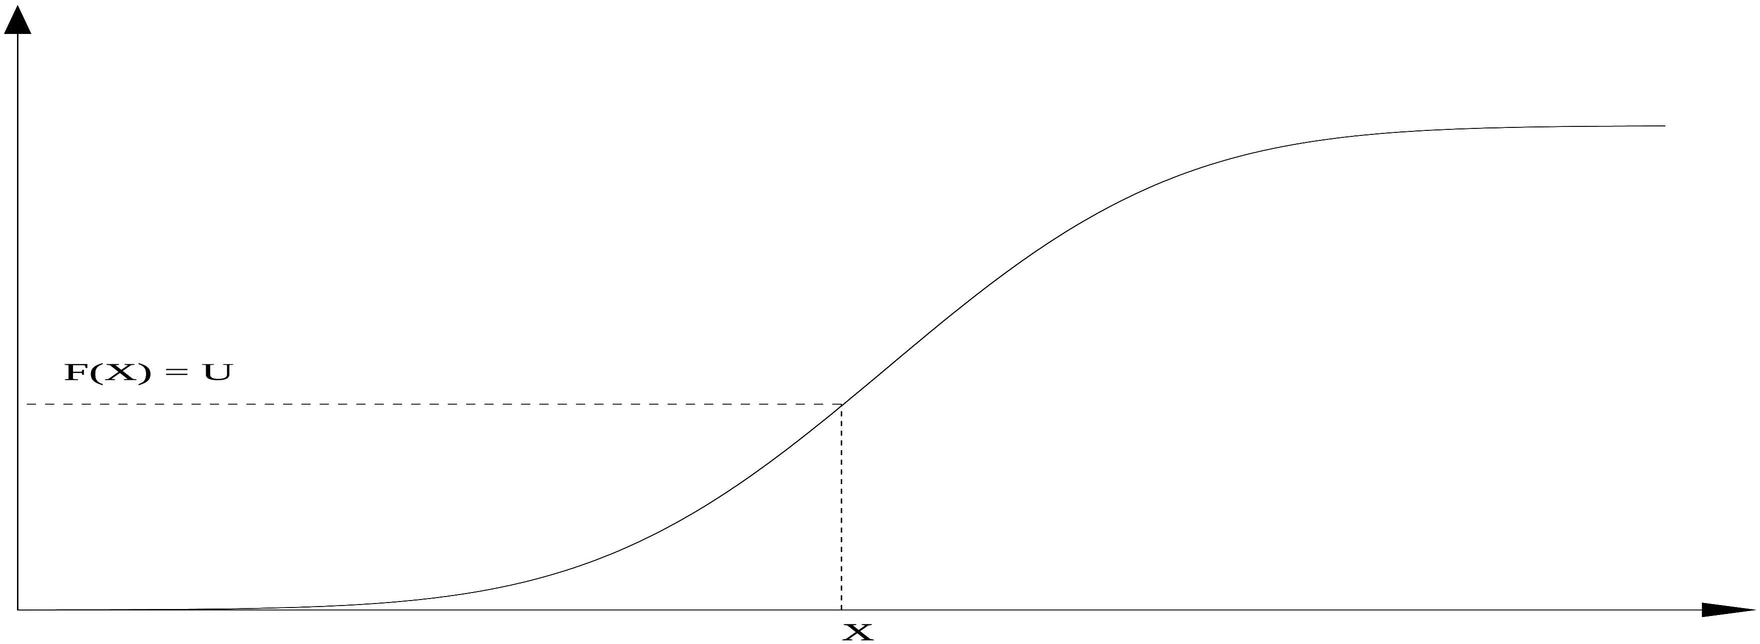
Inverse transformation

The cumulative distribution function (CDF)

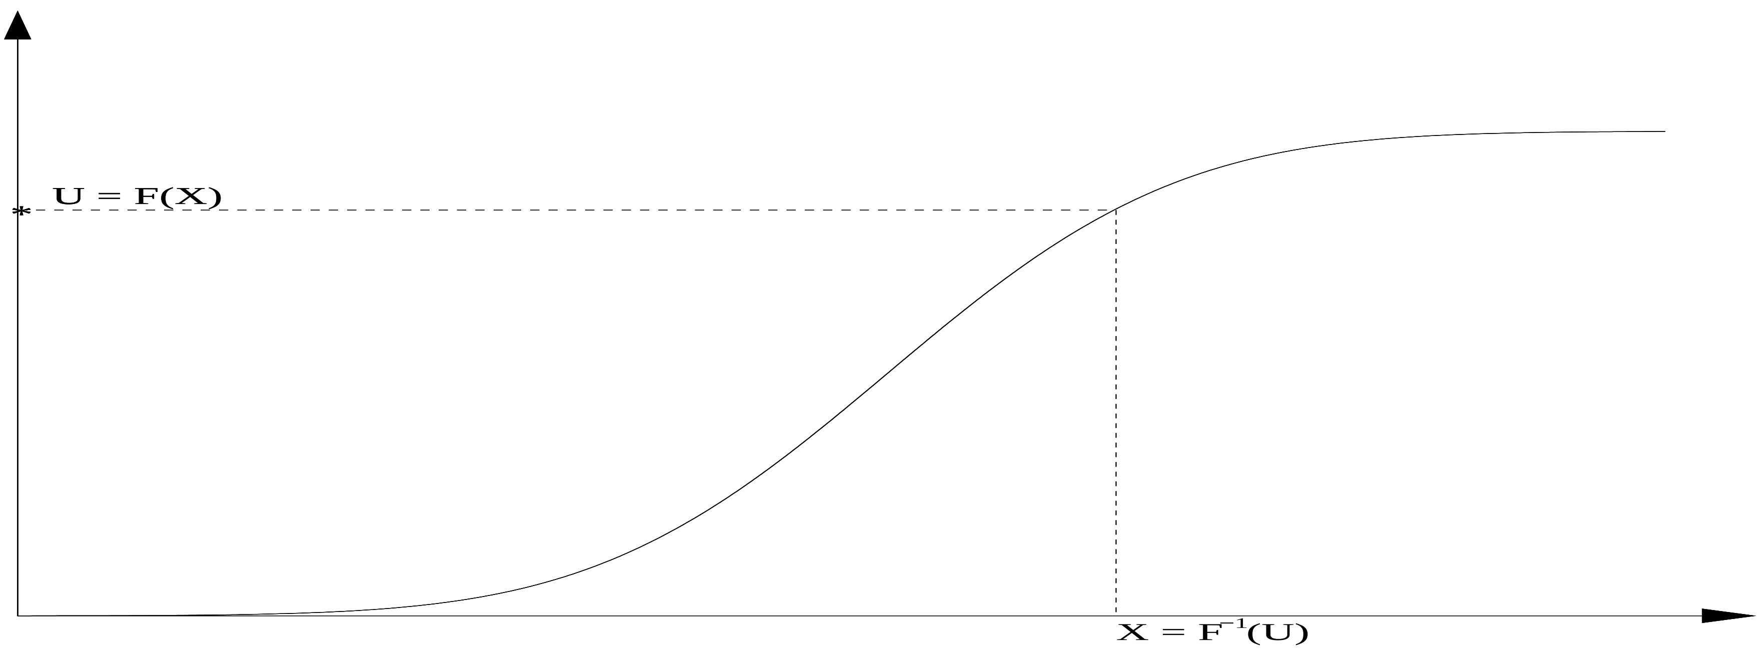
$$F(x) = P(X \leq x)$$



The random variable $F(X)$

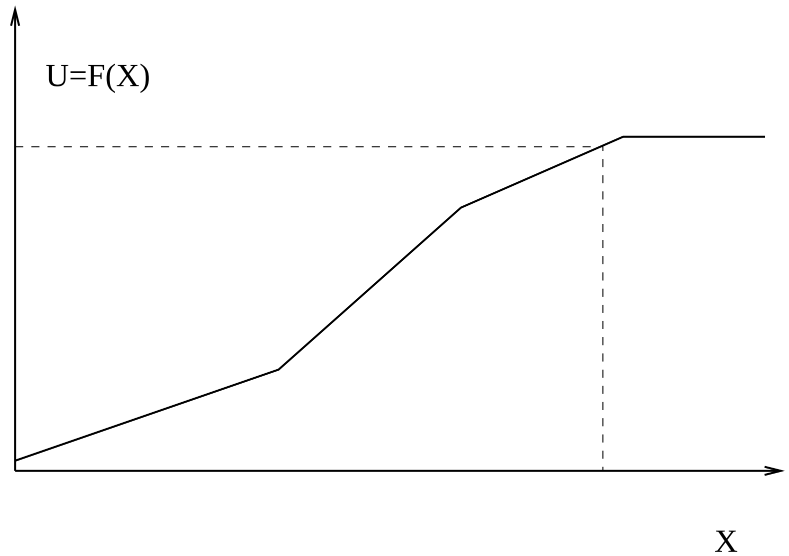


From U to X



Inversion method

The random variable $U = F(X)$



$$U = F(X) \qquad F(x) = P(X \leq x)$$

$$P(U \leq u) = P(F(X) \leq u) = P(X \leq F^{-1}(u)) = F(F^{-1}(u)) = u$$

I.e. $F(X)$ is uniformly distributed.

Inversion method

Assuming C^1 functions (also for g and g^{-1}) and let:

$$X = g(Y) \qquad Y \; F_Y(y) = P(Y \leq y)$$

then

$$F_x(x) = P(X \leq x) = P(g(Y) \leq x) = P(Y \leq g^{-1}(x)) = F_y(g^{-1}(x))$$

If $Y = U$ then $F_u(u) = u$, and $F_x(x) = g^{-1}(x)$.
If

$$\boxed{X = F^{-1}(U)}$$

then X will have the cdf $F(x)$.

Uniform distribution II

Now, focus on $U(a,b)$.

$$f(x) = \frac{1}{b-a} \qquad a \leq x \leq b$$

$$F(x) = \frac{x-a}{b-a} \qquad F^{-1}(u) = a + (b-a)u$$

$$X = a + (b-a)U \qquad \sim \qquad U(a,b)$$

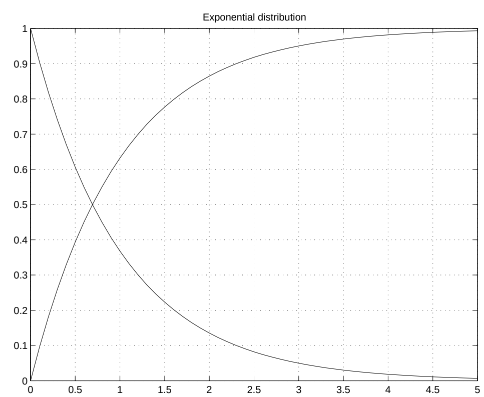
Exponential distribution

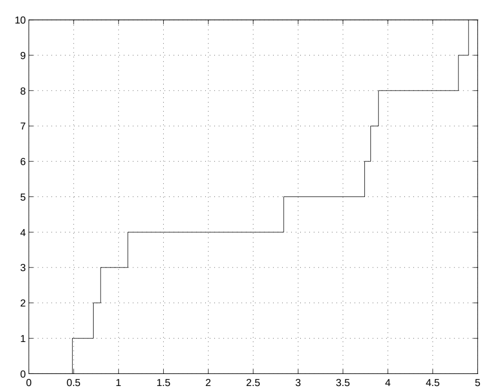
The time between events in a Poisson process is exponentially distributed. (Arrival time)

$$F(x) = 1 - e^{(-\lambda x)} \quad \mathbb{E}(X) = \frac{1}{\lambda} \quad F^{-1}(u) = -\frac{1}{\lambda}\log(1-u)$$

So (both $1-U$ and U is uniform distributed)

$$X = -\frac{\log(U)}{\lambda} \sim \exp(\lambda)$$



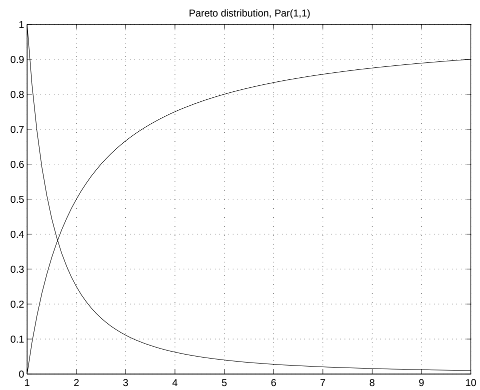


Pareto

Is often used in connection to description of income (over a certain level).

$$X \sim Pa(k,\beta) \quad F(x) = 1 - \left(\frac{\beta}{x}\right)^k \quad x \geq \beta \;\; X = \beta\left(U^{-\frac{1}{k}}\right)$$

$$\mathbb{E}(X) = \frac{k}{k-1}\beta \quad \mathbb{V}(X) = \frac{k}{(k-1)^2(k-2)}\beta^2 \quad k > 1,\; 2$$



Pareto with $X \geq 0$

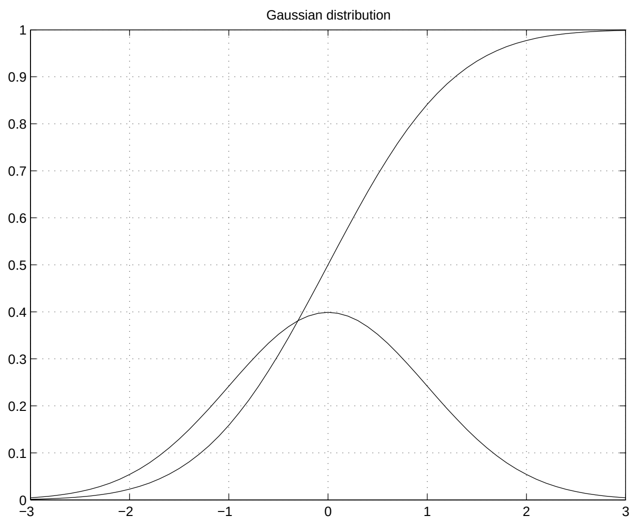
$$F(x) = 1 - \left(1 + \frac{x}{\beta}\right)^{-k} \quad X = \beta\left(U^{-\frac{1}{k}} - 1\right)$$

Gaussian

X a result of many (∞) independent sources (Central limit theorem)

$$X \sim \mathbb{N}(\mu, \sigma^2)$$

$$Z \sim \mathbb{N}(0,1) \qquad X = \mu + \sigma Z \qquad Z = \Phi^{-1}(U)$$



Mathematical Method

- By means of transformation and other techniques we can obtain stochastic variable with a certain distribution.

The Box-Muller method A transformation from polar ($\theta = 2\pi U_2$, $r = \sqrt{-2\log(U_1)}$) into Cartesian coordinates ($X = Z_1$ and $Y = Z_2$).

$$\begin{bmatrix} Z_1 \\ Z_2 \end{bmatrix} = \sqrt{-2\log(U_1)} \begin{bmatrix} \cos(2\pi U_2) \\ \sin(2\pi U_2) \end{bmatrix} \qquad Z_1,\ Z_2 \sim \mathbb{N}(0,1)$$

Central limit theorem

$$X = \sum_{i=1}^{n} U_i - \frac{n}{2} \qquad \text{eg.} \quad n = 6$$

Generation of $\cos$ and $\sin$

Sine and cosine can be calculated by the following acceptance/rejection algorith m:

1. Generate $V_1, V_2 \sim U(0,1)$
2. Generate $R^2 = V_1^2 + V_2^2$
3. If $R^2 > 1$ goto 1.
4. $\cos(2\pi U_2) = \frac{V_1}{R}, \sin(2\pi U_2) = \frac{V_2}{R}$

Logarithmic Gaussian, $LN(\alpha, \beta^2)$

$$Y \sim LN(\alpha, \beta^2) \qquad \log(Y) \sim \mathbb{N}(\alpha, \beta^2)$$

$$Y = e^X \qquad X = \alpha + \beta\ Z \qquad Z \sim N(0, 1)$$

General and mulitvariate normal distribution

- Generate n independent values from an $N(0,1)$ distribution,$Z_i \sim N(0,1)$.
- $X_i = \mu_i + \sum_{j=1}^{i} c_{ij} Z_j$
- Where c_{ij} are the elements in the Cholesky factorisation of $\Sigma, \Sigma = CC'$

Composition methods - hyperexponential distribution

$$F(x) = 1 - \sum_{i=1}^{m} p_i e^{-\lambda_i x} = \sum_{i=1}^{m} p_i \left(1 - e^{-\lambda_i x}\right)$$

Formally we can express

$Z = X_I$ where $I \sim \{1, 2, \ldots, m\}$ with $P(I = i) = p_i$ and $X_I \sim \exp(\lambda_I)$

1. Choose $I \sim \{1, 2, \ldots, m\}$ with probabilities p_i's
2. $Z = -\frac{1}{\lambda_I} \log(U)$

Composition methods - Erlang distribution

- The Erlang distribution is a special case of the Gamma distribution with integer valued shape parameter
- An Erlang distributed random variable can be interpreted as a sum of independent exponential variables
- We can generate an Erlang-n distributed random variate by adding n exponential random variates.

$$Y \sim \mathsf{Erl}_n(\lambda) \qquad \mathbb{E}(Y) = \frac{n}{\lambda} \qquad \mathbb{V}(Y) = \frac{n}{\lambda^2}$$

with $\lambda_i = \lambda$

$$Y = \sum_{i=1}^{n} X_i = \sum_{i=1}^{n} -\frac{1}{\lambda} \log\left(U_i\right) = -\frac{1}{\lambda} \log\left(\Pi_{i=1}^{n} U_i\right)$$

Composition methods II

Generalization:

$$f(x) = \int f(x|y) f(y) dy$$

$$X \text{ given } Y : f(x|y) \qquad Y : f(y)$$

Y is typically a parameter (eg. the conditional distribution of X given $Y = \mu$ is $\mathbb{N}(\mu, \sigma^2)$)

Generate:

- Generate Y from $f(y)$.
- Generate X from $f(x|y)$ where Y is used.

Acceptance/rejection

Problem: we would like to generate X from pdf f, but it is much faster to generate Y
with pdf g. NB. X and Y have the same sample space. If

$$\frac{f(y)}{g(y)} \leq c \qquad \text{for all } y \text{ and some } c$$

- Step 1. Generate Y having density g.
- Step 2. Generate a random number U
- If $U \leq \frac{f(Y)}{cg(Y)}$ set $X = Y$.Otherwise return to step 1.

$$g(y)dy\frac{f(y)}{cg(y)} = \frac{f(y)dy}{c}$$

Exercise 3

- Generate simulated values from the following distributions
  - Exponential distribution
  - Normal distribution (at least with Box-Mueller)
  - Pareto distribution, with $\beta = 1$ and experiment with different values of k values: k = 2.05, k = 2.5, k = 3 og k = 4.
- Verify the results by comparing histograms with analytical results and erform tests for distribution type.
- For the Pareto distribution with support on $[\beta, \infty[$ compare mean value and variance, with analytical results, which can be calculated as $E\{X\} = \beta\frac{k}{k-1}$ (for $k > 1$) and $Var\{X\} = \beta^2\frac{k}{(k-1)^2(k-2)}$ (for $k > 2$)

Exercise 3 continued

- For the normal distribution generate 100 95% confidence intervals for the mean and variance based on 10 observations. Discuss the results.
